

# Diarrhea

---

## **WHAT IS DIARRHEA?**

Diarrhea is an increase in the water content, frequency, and volume of bowel movements. It is frequent in people with [HIV](#).

Diarrhea can be a serious problem. Mild cases disappear within a few days but more severe cases can cause serious dehydration or nutritional problems.

## **IS DIARRHEA DANGEROUS?**

The greatest risk of diarrhea is dehydration. You can lose up to a gallon of water each day. Along with the water, you lose minerals (electrolytes) that are important for normal body functions. The main electrolytes are sodium and potassium.

Severe dehydration can cause the body to go into shock and is potentially fatal. Dehydration is more serious for infants and children than for adults. Anyone with diarrhea should drink plenty of clear liquids. Tea, broth, ginger ale, or other non-caffeinated sodas are good choices. These are better than plain water, which does not replace any electrolytes.

Diarrhea that continues over a long period of time can cause poor absorption of nutrients. This can lead to wasting.

Diarrhea can be dangerous. Be sure your healthcare provider knows if your diarrhea lasts more than a few days.

## **WHAT CAUSES DIARRHEA?**

It can be difficult to find out what is causing diarrhea. Diarrhea is sometimes caused by an infection in the stomach or intestines. Bacteria, parasites, fungi, or viruses can cause the infection.

- **Parasites:** The parasites [cryptosporidium](#) or microsporidium used to cause diarrhea in many people with HIV. The use of combination [antiretroviral therapy \(ART\)](#) has greatly reduced the rates of these problems.
- **Antiretroviral Medications (ARVs):** These can cause diarrhea. This is often true with nelfinavir (Viracept), [ritonavir \(Norvir\)](#), [Kaletra \(lopinavir plus ritonavir\)](#), didanosine (Videx), foscarnet (Foscavir), tipranavir (Aptivus) and interferon alfa (Roferon or Intron).
- **Other causes:** Taking antibiotics can kill off good bacteria in your gut and may cause diarrhea.

Diarrhea can also be caused by an inability to digest milk products (lactose intolerance), problems with the pancreas, or emotional stress.

### **HOW DO I KNOW WHAT IS CAUSING MY DIARRHEA?**

Your healthcare provider will ask you what you have been eating and drinking recently, and whether you have been traveling. Samples of your bowel movements (or stool) may be tested for signs of bacteria or parasites. Your healthcare provider may repeat this test if nothing shows up the first time. In some cases, your blood or urine will also be tested.

If these tests do not show the cause of diarrhea, your healthcare provider may look inside your digestive tract with a special tool or scope. The name of this procedure depends on where the healthcare provider is looking. Endoscopy is a general term that means to look inside. A colonoscopy is a procedure where the healthcare provider examines the colon. The cause of about one third of all cases of diarrhea cannot be determined.

### **HOW IS DIARRHEA TREATED?**

**Change what you eat:** Some foods can cause diarrhea and others can help stop it.

<b>DON'T EAT</b>	<b>DO EAT</b>
Dairy products (milk or cheeses)	Bananas
Greasy or fried food	Plain white rice
Fatty foods including butter, margarine, oils, or nuts	Applesauce
Spicy foods	Oatmeal or cream of wheat
Foods high in "insoluble" fiber (includes raw fruits and vegetables, whole wheat bread, corn, or any fruit or vegetable skins or seeds)	Toasted white bread or plain crackers
	Plain macaroni or noodles
	Boiled eggs
	Mashed potatoes
	Yogurt (this is a dairy product, but it's partially digested by the bacteria used to make it and therefore easy for the body to metabolize)

**Drug treatments:** A treatment for HIV-associated diarrhea is Fulyzaq (crofelemer.) It was approved by the FDA late in 2012. Different medications are used to treat different types of diarrhea. Your healthcare provider may not be able to prescribe a medication without some idea of what is causing your diarrhea.

You do not need a prescription for over-the-counter (OTC) treatments. Some of these work very well for diarrhea, including:

- The amino acid L-glutamine
- Pepto-Bismol (Bismuth subsalicylate)
- Kaopectate (attapulgite)
- Imodium AD (loperamide)

Some other products that are usually sold to treat constipation can also help with diarrhea. These products, such as Metamucil, Citrucel, or other products that contain psyllium, contain soluble fiber that adds bulk and absorbs water.

## **ALTERNATIVE THERAPIES FOR DIARRHEA**

Acidophilus capsules (which contain helpful bacteria) can help restore normal digestion, especially when you are taking antibiotics. Some types of yogurt contain live cultures of acidophilus that work the same way.

Peppermint, ginger, and nutmeg are believed to help with digestive problems. Peppermint or ginger tea or ginger ale would be good choices for clear liquids. Try adding nutmeg to your food or drinks.

Studies have shown that calcium supplements helped relieve diarrhea in people taking the [protease inhibitor](#) nelfinavir (Viracept). This might work for diarrhea caused by other medications

## **THE BOTTOM LINE**

Diarrhea is a common problem for people with HIV. It is usually caused by an infection in the digestive system. Stress, some medications, or problems digesting milk products can also cause diarrhea.

The most serious result is dehydration. This is more of a problem for children than for adults. If you have diarrhea, you should drink plenty of clear liquids.

Some simple changes in your food can help with diarrhea. So can some over the counter (OTC) medications or acidophilus.

Be sure you tell your healthcare provider if your diarrhea lasts more than a few days.
